Arrows for Parallel Computations

MARTIN BRAUN University Bayreuth, 95440 Bayreuth, Germany PHIL TRINDER Glasgow University, Glasgow, G12 8QQ, Scotland and OLEG LOBACHEV University Bayreuth, 95440 Bayreuth, Germany

Abstract

Arrows are a general interface for computation and therefore form an alternative to Monads for API design. We express parallelism using this concept in a novel way: We define an arrows-based language for parallelism and implement it using multiple parallel Haskells. In this manner we are able to bridge across various parallel Haskells.

Additionally, our way of writing parallel programs has the benefit of being portable across flavours of parallel Haskells. Furthermore, as each parallel computation is an arrow, which means that they can be composed and transformed as such. We introduce some syntactic sugar to provide parallelism-aware arrow combinators.

To show that our arrow-based language is on par with the existing parallel languages, we also define several parallel skeletons with our framework. Benchmarks show that our framework does not induce too much overhead performance-wise. OL: Summarize conclusions

1 Introduction

OL: todo, reuse 5.5, and more

MB: Haskell is Spielwiese für Parallelität; verschiedene Ansätze (Par, Multicore, Eden); Orthogonale Ansätze; Verwenden höchstens eine Monade - manchmal auch nur intern; Wir wollen Parallelität mit Arrows abbilden, was noch niemand gemacht hat; Statt einer eigenen Implementierung definieren wir ein "shallow embedded DSL" (ACHTUNG, ist das der richtige Name? effektiv API); Umsetzung mit verschiedenen parallelen Haskells; We tame the zoo of parallel Haskells und vergewissern uns dass es nicht viel Overhead bringt

blablabla arrows, parallel, haskell.

Contribution OL: HIT HERE REALLY STRONG

MB: different, how? We wrap parallel Haskells inside of our ArrowParallel interface, but why do we aim to abstract parallelism this way and what does this approach do better than the other parallel Haskells?

- Arrow DSL benefits: With the ArrowParallel typeclass we do not lose any benefits of using arrows as parEvalN is a yet another Arrow combinator. The resulting Arrow can be used in the same way a potential serial version could be used. This is a big advantage of this approach, especially compared to the Monad solutions as we do not introduce any new types. We can just 'plug' in parallel parts into sequential Arrow-based programs without having to change anything.
- **Abstraction**: With the *ArrowParallel* typeclass, we abstract all parallel implementation logic away from the business logic. This leaves us in the beautiful situation of being able to write our code against the interface of the typeclass without being bound to any parallel Haskell. So as an example, during development, we can run the program in a simple GHC-compiled variant and afterwards deploy it on a cluster by converting it into an Eden version, by just replacing the actual ArrowParallel instance.

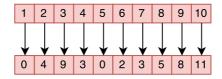

Figure 1: Schematic illustration of parEvalN.

Structure The remaining text is structures as follows. Section 2 briefly introduces known parallel Haskell flavours (Sec. 2.1) and gives an overview of Arrows to the reader (Sec. 2.2). Section 3 discusses related work. Section 4 defines Parallel Arrows and presents a basic interface. Section 5 defines Futures for Parallel Arrows, this concept enables better communication. Section 6 presents some basic algorithmic skeletons in our newly defined dialect: parallel map with and without load balancing. More advanced skeletons are showcased in Section 7 (pipe, ring, torus). Section 8 shows the benchmark results. Section 9 discusses future work and concludes.

2 Background

2.1 Short introduction to parallel Haskells

There are already several ways to write parallel programs in Haskell. As we base our parallel arrows on existing parallel Haskells, we will now give a short introduction to the ones we use as backends in this paper.

In its purest form, parallel computation (on functions) can be looked at as the execution of some functions $a \to b$ in parallel or parEvalN:: $[a \to b] \to [a] \to [b]$, as also Figure 1 symbolically shows. As a demonstration, we implement here the non-Arrows parEvalN in multiple parallel Haskells.

2.1.1 Multicore Haskell

Multicore Haskell (Marlow et al., 2009; Trinder et al., 1998) is a way to do parallel processing found in standard GHC. 1 It ships with parallel evaluation strategies for several types which can be applied with using :: $a \rightarrow Strategy \ a \rightarrow a$. Let:

```
parEvalN :: (NFData\ b) \Rightarrow [a \rightarrow b] \rightarrow [a] \rightarrow [b]
parEvalN \ fs \ as = let \ bs = zipWith \ (\$) \ fs \ as
   in (bs 'using' parList rdeepseq) 'pseq' bs
```

In the above definition of parEvalN we just apply the list of functions $[a \rightarrow b]$ to the list of inputs [a] by zipping them with the application operator \$. We then evaluate this lazy list [b] according to a Strategy [b] with the using:: $a \to Strategy \ a \to a$ operator. We construct this strategy with parList:: Strategy $a \to Strategy[a]$ and rdeepseq:: NFData $a \Rightarrow Strategy[a]$

¹ Multicore Haskell on Hackage is available under https://hackage.haskell.org/package/ parallel-3.2.1.0, compiler support is integrated in the stock GHC.

4

M. Braun, P. Trinder, and O. Lobachev

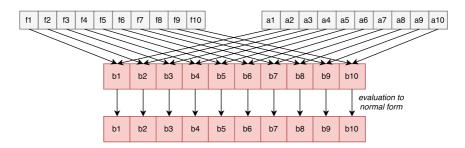

Figure 2: Dataflow of the Multicore Haskell parEvalN version.

where the latter is a strategy which evalutes to normal form. To ensure that programs that use parEvalN have the correct evaluation order, we annotate the computation with $pseq: a \rightarrow b \rightarrow b$ which forces the compiler to not reorder multiple parEvalN computations. This is particularly necessary in circular communication topologies like in the torus or ring (Chap. 7), where a wrong execution order would result in deadlock scenarios when executed without pseq. Fig. 2 shows a visual representation of this code.

2.1.2 Par Monad

The Par Monad² introduced by Marlow et al. (2011), is a Monad designed for composition of parallel programs. Let:

```
parEvalN :: (NFData\ b) \Rightarrow [a \rightarrow b] \rightarrow [a] \rightarrow [b]
parEvalN fs as = runPar $
   (sequenceA \$ map (spawnP) \$ zipWith (\$) fs as) > mapM get
```

The Par Monad version of our parallel evaluation function parEvalN is defined by zipping the list of $[a \rightarrow b]$ with the list of inputs [a] with the application operator \$ just like with Multicore Haskell. Then, we map over this not yet evaluated lazy list of results [b] with $spawnP :: NFData \ a \Rightarrow a \rightarrow Par \ (IVar \ a)$ to transform them to a list of not yet evaluated forked away computations [Par (IVar b)], which we convert to Par [IVar b] with sequenceA. We wait for the computations to finish by mapping over the *IVar b* values inside the *Par* Monad with get. This results in Par[b]. We execute this process with runPar to finally get [b]. Fig. 3 shows a graphical representation.

2.1.3 Eden

Eden (Loogen et al., 2005; Loogen, 2012) is a parallel Haskell for distributed memory and comes with a MPI and a PVM backends.³ It is targeted towards clusters, but also functions well in a shared-memory setting with a further simple backend. However, in contrast to many other parallel Haskells, in Eden each process has its own heap. This seems to be

² It can be found in the monad-par package on hackage under https://hackage.haskell.org/ package/monad-par-0.3.4.8/.

See also http://www.mathematik.uni-marburg.de/~eden/ and https://hackage. ${\tt haskell.org/package/eden modules-1.2.0.0/}.$

Arrows for Parallel Computations

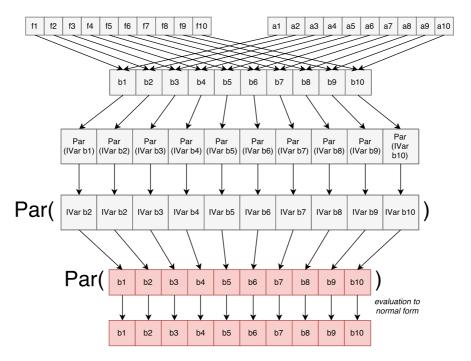

Figure 3: Dataflow of the Par Monad parEvalN version.

a waste of memory, but with distributed programming paradigm and individual GC per process, Eden yields good performance results also on multicores (Berthold *et al.*, 2009a; Aswad *et al.*, 2009).

While Eden also comes with a Monad PA for parallel evaluation, it also ships with a completely functional interface that includes a spawnF:: $(Trans\ a, Trans\ b) \Rightarrow [a \rightarrow b] \rightarrow [a] \rightarrow [b]$ function that allows us to define parEvalN directly:

$$parEvalN :: (Trans\ a, Trans\ b) \Rightarrow [a \rightarrow b] \rightarrow [a] \rightarrow [b]$$

 $parEvalN = spawnF$

Eden TraceViewer. To comprehend the efficiency and the lack thereof in a parallel program, an inspection of its execution is extremely helpful. While some large-scale solutions exist (Geimer *et al.*, 2010), the parallel Haskell community mainly utilises the tools Threadscope (Wheeler & Thain, 2009) and Eden TraceViewer⁴ (Berthold & Loogen, 2007). In the next sections we will present some *trace visualizations*, the post-mortem process diagrams of Eden processes and their activity.

The trace visualizations are color-coded. In such a visualization (Fig. 13), the *x* axis shows the time, the *y* axis enumerates the machines and processes. The visualization shows a running process in green, a blocked process is red. If the process is 'runnable', i.e. it may run, but does not, it is yellow. The typical reason for thus is GC. An inactive machine,

⁴ See http://hackage.haskell.org/package/edentv on Hackage for the last available version of Eden TraceViewer.

```
class Arrow arr where
   arr :: (a \rightarrow b) \rightarrow arr \ a \ b

where no processes are started yet, or all are already terminated, shows as a blue bar. A comminication from one process to another is represented with a black arrow. A stream of communications, e.g. a transmitted list is shows as a dark shading between sender and receiver processes.

2.2 Arrows

Arrows were introduced by Hughes (2000) as a general interface for computation. An Arrow arr a b represents a computation that converts an input a to an output b. This is defined in the Arrow type class shown in Fig. 4. Its arr operation is used to lift an ordinary function to the specified arrow type, similarly to the monadic return. The >>> operator is analogous to the monadic composition \gg and combines two arrows arr a b and arr b c by "wiring" the outputs of the first to the inputs to the second to get a new arrow arr a c. Lastly, the first operator takes the input arrow from b to c and converts it into an arrow on pairs with the

second argument untouched. It allows us to to save input across arrows. Figure 5 shows a graphical representation of the basic Arrow combinators. The most prominent instances of this interface are regular functions (\rightarrow) and the Kleisli type (Fig. 4).

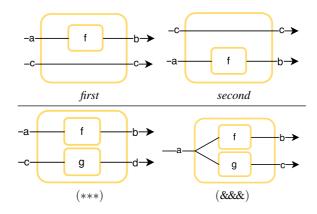

Figure 6: Visual depiction of syntactic sugar for Arrows.

With this typeclass in place, Hughes also defined some syntactic sugar (Fig. 6): The combinators second, *** and &&&. The combinator second is the mirrored version of first (Appendix A). The *** function combines first and second to handle two inputs in one arrow, is defined as

```
(***)::Arrow arr \Rightarrow arr a b \rightarrow arr c d \rightarrow arr (a,c) (b,d)
f *** g = first f >>> second g
```

while the &&& combinator, that constructs an arrow which outputs two different values like ***, but takes only one input, is:

```
(\&\&\&):: Arrow arr \Rightarrow arr \ a \ b \rightarrow arr \ a \ c \rightarrow a \ a \ (b,c)
f \&\&\& g = arr (\lambda a \to (a,a)) >>> (f ***g)
```

A first short example given by Hughes on how to use arrows is addition with arrows:

```
add::Arrow arr \Rightarrow arr \ a \ Int \rightarrow arr \ a \ Int \rightarrow arr \ a \ Int
add f g = (f \&\&\& g) >>> arr (\lambda(u,v) \rightarrow u + v)
```

The more restrictive interface of Arrows allows for more elaborate composition and transformation combinators—a Monad can be anything, an Arrow is a process of doing something, a *computation*. One of the major problems in parallel computing is, however, composition of parallel processes.

3 Related Work

Parallel Haskells. Of course, the three parallel Haskell flavours we have presented above: the GpH (Trinder et al., 1996, 1998) parallel Haskell dialect and its multicore version (Marlow et al., 2009), the Par Monad (Marlow et al., 2011; Foltzer et al., 2012), and Eden

(Loogen et al., 2005; Loogen, 2012) are related to this work. We use these languages as backends: our DSL can switch from one to other at user's command.

HdpH (Maier et al., 2014; Stewart et al., 2016) is an extension of Par Monad to heterogeneous clusters. LVish (Kuper et al., 2014) is a communication-centred extension of Par Monad. Further parallel Haskell approaches include pH (Nikhil & Arvind, 2001), research work done on distributed variants of GpH (Trinder et al., 1996; Aljabri et al., 2014, 2015), and low-level Eden implementation (Berthold, 2008; Berthold et al., 2016). Skeleton composition (Dieterle et al., 2016), communication (Dieterle et al., 2010a), and generation of process networks (Horstmeyer & Loogen, 2013) are recent in-focus research topics in Eden. This also includes the definitions of new skeletons (Hammond et al., 2003; Berthold & Loogen, 2006; Berthold et al., 2009b,c; Dieterle et al., 2010b; de la Encina et al., 2011; Dieterle et al., 2013; Janjic et al., 2013).

More different approaches include data parallelism (Chakravarty et al., 2007; Keller et al., 2010), GPU-based approaches (Mainland & Morrisett, 2010; Svensson, 2011), software transactional memory (Harris et al., 2005; Perfumo et al., 2008). The Haskell-GPU bridge Accelerate (Chakravarty et al., 2011; Clifton-Everest et al., 2014; McDonell et al., 2015) deserves a special mention. Accelerate is completely orthogonal to our approach. Marlow authored a recent book in 2013 on parallel Haskells.

Algorithmic skeletons. Algorithmic skeletons were introduced by Cole (1989). Early publications on this topic include (Darlington et al., 1993; Botorog & Kuchen, 1996; Danelutto et al., 1997; Gorlatch, 1998; Lengauer et al., 1997). Rabhi & Gorlatch (2003) consolidated early reports on high-level programming approaches. The effort is ongoing, including topological skeletons (Berthold & Loogen, 2006), special-purpose skeletons for computer algebra (Berthold et al., 2009c; Lobachev, 2011, 2012; Janjic et al., 2013), iteration skeletons (Dieterle et al., 2013). The idea of Linton et al. (2010) is to use a parallel Haskell to orchestrate further software systems to run in parallel. Dieterle et al. (2016) compare the composition of skeletons to stable process networks.

Arrows. Arrows were introduced by Hughes (2000), basically they are a generalised function arrow \rightarrow . Hughes (2005a) presents a tutorial on Arrows. Some theoretical details on Arrows (Jacobs et al., 2009; Lindley et al., 2011; Atkey, 2011) are viable. Paterson (2001) introduced a new notation for Arrows. Arrows have applications in information flow research (Li & Zdancewic, 2006, 2010; Russo et al., 2008), invertible programming (Alimarine et al., 2005), and quantum computer simulation (Vizzotto et al., 2006). But probably most prominent application of Arrows is Arrow-based functional reactive programming, AFRP (Nilsson et al., 2002; Hudak et al., 2003; Czaplicki & Chong, 2013). Liu et al. (2009) formally define a more special kind of Arrows that capsule the computation more than regular arrows do and thus enable optimizations. Their approach would allow parallel composition, as their special Arrows would not interfere with each other in concurrent execution. In contrast, we capture a whole parallel computation as a single entity: our main instantiation function parEvalN makes a single (parallel) Arrow out of list of Arrows. Huang et al. (2007) utilise Arrows for parallelism, but strikingly different from our approach. They basically use Arrows to orchestrate several tasks in robotics. We, however, propose a general interface for parallel programming, while remaining completely in Haskell.

Other languages. Although this work is centred on Haskell implementation of arrows, it is applicable to any functional programming language where parallel evaluation and arrows can be defined. Experiments with our approach in Frege language⁵ (which is basically Haskell on the JVM) were quite successful. However, it is beyond the scope of this work.

Achten et al. (2004, 2007) use an arrow implementation in Clean for better handling of typical GUI tasks. Dagand et al. (2009) used arrows in OCaml in the implementation of a distributed system.

4 Parallel Arrows

Arrows are a general interface to computation. Here we introduce special Arrows as general interface to parallel computations. First, we present the interface and explain the reasonings behind it. Then, we discuss some implementations using exisiting parallel Haskells. Finally, we explain why using Arrows for expressing parallelism is beneficial.

4.1 The ArrowParallel typeclass

A parallel computation (on functions) in its purest form can be seen as execution of some functions $a \to b$ in parallel, as our *parEvalN* prototype shows (Sec. 2.1). Translating this into arrow terms gives us a new operator parEvalN that lifts a list of arrows [arr a b] to a parallel arrow arr[a][b]. This combinator is similar to our utility function *listApp* from Appendix A, but does parallel instead of serial evaluation.

```
parEvalN :: (Arrow arr) \Rightarrow [arr a b] \rightarrow arr [a] [b]
```

With this definition of parEvalN, parallel execution is yet another arrow combinator. But as the implementation may differ depending on the actual type of the arrow arr and we want this to be an interface for different backends, we introduce a new typeclass ArrowParallel arr a b:

```
class Arrow \ arr \Rightarrow Arrow Parallel \ arr \ a \ b where
   parEvalN :: [arr \ a \ b] \rightarrow arr \ [a] \ [b]
```

Sometimes parallel Haskells require or allow for additional configuration parameters, e.g. an information about the execution environment or the level of evaluation (weak head normal form vs. normal form). For this reason we also introduce an additional *conf* parameter to the function. We also do not want *conf* to be a fixed type, as the configuration parameters can differ for different instances of ArrowParallel.

```
class Arrow arr \Rightarrow Arrow Parallel arr a b conf where
   parEvalN :: conf \rightarrow [arr \ a \ b] \rightarrow arr \ [a] \ [b]
```

We do not require the *conf* parameter in every implementation. If it is not needed, we usually just default the conf type parameter to () and even blank it out in the parameter list of the implemented parEvalN.

⁵ GitHub project page at https://github.com/Frege/frege

20:58

```
data Conf a = Conf (Strategy a)
instance (NFData b, ArrowApply arr, ArrowChoice arr) \Rightarrow ArrowParallel arr a b () where
  parEvalN \_fs =
    listApp fs >>>
    arr (withStrategy (parList rdeepseq)) &&& arr id >>>
    arr (uncurry pseq)
```

Figure 7: Fully evaluating ArrowParallel instance for the Multicore Haskell backend.

```
instance (NFData b, ArrowApply arr, ArrowChoice arr) \Rightarrow
  ArrowParallel arr a b (Conf b) where
  parEvalN (Conf strat) fs =
     listApp fs >>>
     arr (withStrategy (parList strat)) &&& arr id >>>
     arr (uncurry pseq)
```

Figure 8: Configurable ArrowParallel instance for the Multicore Haskell backend.

4.2 ArrowParallel instances

4.2.1 Multicore Haskell

The Multicore Haskell implementation of ArrowParallel is implemented in a straightforward manner by using *listApp* (Appendix A) combined with the *withStrategy*:: Strategy $a \rightarrow a \rightarrow a$ and $pseq: a \rightarrow b \rightarrow b$ combinators from Multicore Haskell, where with Strategy is the same as $using :: a \rightarrow Strategy \ a \rightarrow a$ but with flipped parameters. For most cases a fully evaluating version like in Fig. 7 would probably suffice, but as the Multicore Haskell interface allows the user to specify the level of evaluation to be done via the Strategy interface, our DSL should allow for this. We therefore introduce the Conf a data-type that simply wraps a Strategy a.

4.2.2 Par Monad

OL: introduce a newcommand for par-monad, "arrows", "parrows" and replace all mentions to them to ensure uniform typesetting done!, we write Arrows. also "Monad"? done! The Par Monad implementation (Fig. 9) makes use of Haskells laziness and Par Monad's spawnP:: NFData $a \Rightarrow a \rightarrow Par$ (IVar a) function. The latter forks away the computation of a value and returns an *IVar* containing the result in the *Par* Monad.

We therefore apply each function to its corresponding input value with and then fork the computation away with arr spawnP inside a zipWithArr (Fig. A 3) call. This yields a list [Par(IVar b)], which we then convert into Par[IVar b] with arr sequence A. In order to wait for the computation to finish, we map over the IVars inside the Par Monad with arr (>= mapM get). The result of this operation is a Par [b] from which we can finally remove the Monad again by running arr runPar to get our output of [b].

```
instance (NFData b,ArrowApply arr,ArrowChoice arr) \Rightarrow ArrowParallel arr a b conf where parEvalN _fs = (arr $\lambda as \rightarrow (fs, as)) >>> zipWithArr (app >>> arr spawnP) >>> arr sequenceA >>> arr (>>=mapM get) >>> arr runPar
```

Figure 9: ArrowParallel instance for the Par Monad backend.

```
4.2.3 Eden
```

For both the Multicore Haskell and *Par* Monad implementations we could use general instances of *ArrowParallel* that just require the *ArrowApply* and *ArrowChoice* typeclasses. With Eden this is not the case as we can only spawn a list of functions and we cannot extract simple functions out of arrows. While we could still manage to have only one class in the module by introducing a typeclass:

```
class (Arrow arr) \Rightarrow Arrow Unwrap arr where arr <math>ab \rightarrow (a \rightarrow b)
```

However, we avoid doing so for aesthetic resons. For now, we just implement *ArrowParallel* for normal functions:

```
instance (Trans\ a, Trans\ b) \Rightarrow ArrowParallel\ (\rightarrow)\ a\ b\ conf\ where parEvalN\ _fs\ as = spawnF\ fs\ as and the Kleisli type: 

instance (Monad\ m, Trans\ a, Trans\ b, Trans\ (m\ b)) \Rightarrow ArrowParallel\ (Kleisli\ m)\ a\ b\ conf\ where parEvalN\ conf\ fs = (arr\ parEvalN\ conf\ (map\ (\lambda(Kleisli\ f) \to f)\ fs)) >>> (Kleisli\ \$\ sequence)
```

4.3 Extending the Interface

With the *ArrowParallel* typeclass in place and implemented, we can now implement some further basic parallel interface functions. These are algorithmic skeletons that, however, mostly serve as a foundation to further, more specific algorithmic skeletons.

```
4.3.1 Lazy parEvalN
```

The function parEvalN is 100% strict, which means that it fully evaluates all passed arrows. Sometimes this might not be feasible, as it will not work on infinite lists of functions like e.g. $map\ (arr \circ (+))\ [1..]$ or just because we need the arrows evaluated in chunks. parEvalNLazy (Figs. 10, 11) fixes this. It works by first chunking the input from [a] to [[a]]

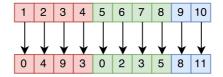

Figure 10: Schematic depiction of parEvalNLazy.

```
parEvalNLazy :: (ArrowParallel \ arr \ a \ b \ conf \ , ArrowChoice \ arr \ , ArrowApply \ arr) \Rightarrow \\ conf \ \rightarrow ChunkSize \ \rightarrow [arr \ a \ b] \ \rightarrow (arr \ [a] \ [b]) \\ parEvalNLazy \ conf \ chunkSize \ fs = \\ arr \ (chunksOf \ chunkSize) >>> \\ listApp \ fchunks >>> \\ arr \ concat \\ \textbf{where} \ fchunks = map \ (parEvalN \ conf) \ \$ \ chunksOf \ chunkSize \ fs
```

Figure 11: Definition of *parEvalNLazy*.

with the given ChunkSize in arr (chunksOf chunkSize). These chunks are then fed into a list [arr [a] [b]] of parallel arrows created by feeding chunks of the passed ChunkSize into the regular parEvalN by using listApp. The resulting [[b]] is lastly converted into [b] with arr concat.

4.3.2 Heterogenous tasks

We have only talked about the paralellization arrows of the same type until now. But sometimes we want to paralellize heterogenous types as well. However, we can implement such a parEval2 combinator (Figs. 12, B 11) which combines two arrows $arr\ a\ b$ and $arr\ c\ d$ into a new parallel arrow $arr\ (a,c)\ (b,d)$ quite easily with the help of the ArrowChoice typeclass. The idea is to use the +++ combinator which combines two arrows $arr\ a\ b$ and $arr\ c\ d$ and transforms them into $arr\ (Either\ a\ c)\ (Either\ b\ d)$ to get a common arrow type that we can then feed into parEvalN.

5 Futures

Consider a mock-up parallel arrow combinator:

```
someCombinator :: (Arrow \ arr) \Rightarrow [arr \ a \ b] \rightarrow [arr \ b \ c] \rightarrow arr \ [a] \ [c]
someCombinator \ fs1 \ fs2 = parEvalN \ () \ fs1 >>> rightRotate >>>> parEvalN \ () \ fs2
```

Figure 12: Schematic depiction of parEval2.

While the above example could be rewritten into only one *parEvalN* call by directly wiring the arrows properly together, it illustrates an important problem. When using a *ArrowParallel* backend that resides on multiple computers, all communication between the nodes is done via the master node, as shown in the Eden trace in Figure 13. This can become a serious bottleneck for larger amount of data and number of processes (as e.g. Berthold *et al.*, 2009c, showcases).

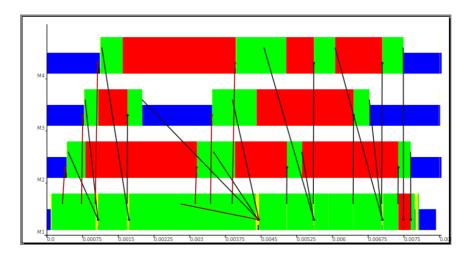

Figure 13: Communication between 4 Eden processes without Futures. All communication goes through the master node. Each bar represents one process. Black lines between processes represent communication. Colors: blue $\hat{=}$ idle, green $\hat{=}$ running, red $\hat{=}$ blocked, yellow $\hat{=}$ suspended.

OL: more practical and heavy-weight example! fft (I have the code)?

MB: Depends... Are the communications easy to read in such an example?

MB: Keep the description for the different colours, or link to the EdenTV description in 2.1.3

OL: ok as is OL: use the fft example (when it works)?

We should allow the nodes to communicate directly with each other. Eden already ships with "remote data" that enable this (Alt & Gorlatch, 2003; Dieterle *et al.*, 2010a). But as we want code with our DSL to be implementation agnostic, we have to wrap this context. We do this with the *Future* typeclass (Fig. 14). Since *RD* is only a type synonym for a communication type that Eden uses internally, we have to use some wrapper classes to fit that definition, though, as Fig. B 5 shows. Technical details are in Appendix, in Section B.

For our *Par* Monad and Multicore Haskell backends, we can simply use *BasicFutures* (Fig. 15) which are just simple wrappers around the actual data, as in a shared memory setting we do not require Eden's sophisticated communication channels.

```
class Future fut a \mid a \rightarrow fut where

put :: (Arrow \ arr) \Rightarrow arr \ a \ (fut \ a)

get :: (Arrow \ arr) \Rightarrow arr \ (fut \ a) \ a
```

Figure 14: Definition of the *Future* typeclass.

```
data BasicFuture\ a = BF\ a

instance (NFData\ a) \Rightarrow NFData\ (BasicFuture\ a) where

rnf\ (BF\ a) = rnf\ a

instance (NFData\ a) \Rightarrow Future\ BasicFuture\ a where

put = arr\ BF

get = arr\ (\lambda(BF\ a) \rightarrow a)
```

Figure 15: The *BasicFuture* type and its *Future* instance for the *Par* Monad and Multicore Haskell backends.

In our communication example we can use this *Future* concept for direct communications between the nodes as shown in Fig. 16. In a distributed environment, this gives us a

```
someCombinator:: (Arrow \ arr) \Rightarrow [arr \ a \ b] \rightarrow [arr \ b \ c] \rightarrow arr \ [a] \ [c] someCombinator \ fs1 \ fs2 = parEvalN \ () \ (map \ (>>>put) \ fs1) >>> rightRotate >>> parEvalN \ () \ (map \ (get>>>>) \ fs2)
```

Figure 16: The mock-up combinator in parallel.

communication scheme with messages going through the master node only if it is needed—similar to what is shown in the trace visualization in Fig. 17.OL: Fig. is not really clear. Do Figs with a lot of load? — fft?

6 Map-based Skeletons

Now we have developed Parallel Arrows far enough to define some useful algorithmic skeletons that abstract typical parallel computations.

Parallel *map* **and laziness.** The *parMap* skeleton (Figs. B 1, B 2) is probably the most common skeleton for parallel programs. We can implement it with *ArrowParallel* by repeating an arrow *arr a b* and then passing it into *parEvalN* to obtain an arrow *arr* [*a*] [*b*]. Just like *parEvalN*, *parMap* is 100% strict. As *parMap* is 100% strict it has the same restrictions as *parEvalN* compared to *parEvalNLazy*. So it makes sense to also have a *parMapStream* (Figs. B 3, B 4) which behaves like *parMap*, but uses *parEvalNLazy* instead of *parEvalN*. The code is quite straightforward, we show it in Appendix.

20:58

Arrows for Parallel Computations

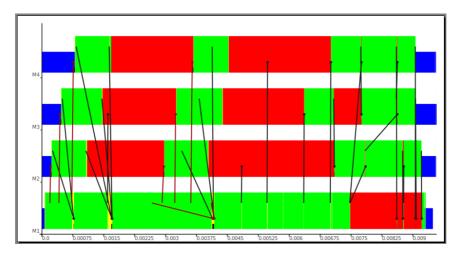

Figure 17: Communication between 4 Eden processes with Futures. Other than in Fig. 13, processes communicate directly (black lines between the bars) instead of always going through the master node (bottom bar).

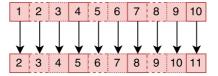

Figure 18: Schematic depiction of a farm, a statically load-balanced parMap.

```
farm::(ArrowParallel arr a b conf,
   ArrowParallel\ arr\ [a]\ [b]\ conf, ArrowChoice\ arr) \Rightarrow
   \mathit{conf} \rightarrow \mathit{NumCores} \rightarrow \mathit{arr} \: a \: b \rightarrow \mathit{arr} \: [a] \: [b]
farm\ conf\ numCores\ f =
   unshuffle numCores>>>
   parEvalN conf (repeat (mapArr f)) >>>
   shuffle
```

Figure 19: The definition of farm.

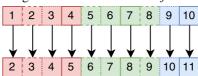

Figure 20: Schematic depiction of farmChunk.

Statically load-balancing parallel map. Our parMap spawns every single computation in a new thread (at least for the instances of ArrowParallel we gave in this paper). This can be quite wasteful and a statically load-balancing farm (Figs. 18, 19) that equally distributes

the workload over numCores workers seems useful. The definitions of the helper functions unshuffle, takeEach, shuffle (Fig. B 6) originate from an Eden skeleton⁶.

Since a farm is basically just parMap with a different work distribution, it is, again, 100% strict. So we can define farmChunk (Figs. 20, B 9) which uses parEvalNLazy instead of parEvalN. It is basically the same definition as for farm, with parEvalN replaced with parEvalNLazy.

7 Topological Skeletons

Even though many algorithms can be expressed by parallel maps, some problems require more sophisticated skeletons. The Eden library leverages this problem and already comes with more predefined skeletons⁷, among them a pipe, a ring, and a torus implementations (Loogen, 2012). These seem like reasonable candidates to be ported to our Arrow-based parallel Haskell. We aim to showcase that we can express more sophisticated skeletons with Parallel Arrows as well.

7.1 Parallel pipe

The parallel *pipe* skeleton is semantically equivalent to folding over a list [arr a a] of arrows with >>>, but does this in parallel, meaning that the arrows do not have to reside on the same thread/machine. We implement this skeleton using the ArrowLoop typeclass which gives us the $loop :: arr(a,b)(c,b) \rightarrow arr\ a\ c$ combinator which allows us to express recursive fix-point computations in which output values are fed back as input. For example

$$loop (arr (\lambda(a,b) \rightarrow (b,a:b)))$$

which is the same as

```
loop (arr snd &&& arr (uncurry (:)))
```

defines an arrow that takes its input a and converts it into an infinite stream [a] of it. Using this to our advantage gives us a first draft of a pipe implementation (Fig. 21) by plugging in the parallel evaluation call parEvalN conf fs inside the second argument of &&& and then only picking the first element of the resulting list with arr last.

However, using this definition directly will make the master node a potential bottleneck in distributed environments as described in Section 5. Therefore, we introduce a more sophisticated version that internally uses Futures and obtain the final definition of pipe in Fig. 22.

Sometimes, this *pipe* definition can be a bit inconvenient, especially if we want to pipe arrows of mixed types together, i.e. arr a b and arr b c. By wrapping these two arrows inside a common type we obtain pipe2 (Fig. 23).

 $^{^{6}\ \} Available\ on\ Hackage\ under\ \texttt{https://hackage.haskell.org/package/edenskel-2.1.0.0/}$ docs/src/Control-Parallel-Eden-Map.html.

20:58

```
pipeSimple :: (ArrowLoop arr, ArrowParallel arr \ a \ a \ conf) \Rightarrow
  conf \rightarrow [arr\ a\ a] \rightarrow arr\ a\ a
pipeSimple conf fs =
  loop (arr snd &&&
      (arr (uncurry (:) >>> lazy) >>> parEvalN conf fs)) >>>
  arr last
```

Figure 21: A first implementation of the *pipe* skeleton expressed with Parallel Arrows. Note that the use of *lazy* (Fig. B 7) is essential as without it programs using this definition would never halt. We need to enforce that the evaluation of the input [a] terminates before passing it into parEvalN.

```
pipe :: (ArrowLoop \ arr, ArrowParallel \ arr \ (fut \ a) \ (fut \ a) \ conf, Future \ fut \ a) \Rightarrow
   conf \rightarrow [arr\ a\ a] \rightarrow arr\ a\ a
pipe\ conf\ fs = unliftFut\ (pipeSimple\ conf\ (map\ liftFut\ fs))
```

Figure 22: Final definition of the *pipe* skeleton with Futures.

```
pipe2:: (ArrowLoop\ arr, ArrowChoice\ arr, Future\ fut\ (([a], [b]), [c]),
   ArrowParallel arr (fut (([a],[b]),[c])) (fut (([a],[b]),[c])) conf) \Rightarrow
   conf \rightarrow arr\ a\ b \rightarrow arr\ b\ c \rightarrow arr\ a\ c
pipe2 conf f g =
   (arr return &&& arr (const [])) &&& arr (const []) >>>
   pipe conf (replicate 2 (unify f(g)) >>>
   arr snd >>> arr head where
      unify :: (ArrowChoice\ arr) \Rightarrow arr\ a\ b \rightarrow arr\ b\ c \rightarrow arr\ (([a],[b]),[c])\ (([a],[b]),[c])
      unify f g =
         (mapArr f *** mapArr g) *** arr ( \longrightarrow []) >>>
         arr (\lambda((a,b),c) \rightarrow ((c,a),b))
(|>>>|):: (ArrowLoop\ arr, ArrowChoice\ arr, Future\ fut\ (([a],[b]),[c]),
   ArrowParallel arr (fut (([a],[b]),[c])) (fut (([a],[b]),[c])) ()) \Rightarrow
   arr\ a\ b \rightarrow arr\ b\ c \rightarrow arr\ a\ c
(|>>>|) = pipe2()
```

Figure 23: Definition of *pipe2* and a parallel >>>.

Note that extensive use of *pipe2* over *pipe* with a hand-written combination data type will probably result in worse performance because of more communication overhead from the many calls to parEvalN. Nonetheless, we can define a version of parallel piping operator |>>>|, which is semantically equivalent to >>> similarly to other parallel syntactic sugar from Appendix C.

```
Another version of >>> is:
f \ parparcomp \ g = (f \circ put) >>> (get \circ g)
```

It does not launch both arrows f and g in parallel, but allows for more smooth data communication between them. Basically, it is a Future-lifted sequential >>>, a way to compose parallel Arrows efficiently.

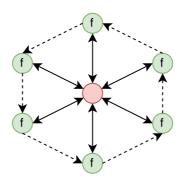

Figure 24: Schematic depiction of the ring skeleton.

7.2 Ring skeleton

Eden comes with a ring skeleton⁸ (Fig. 24) implementation that allows the computation of a function $[i] \rightarrow [o]$ with a ring of nodes that communicate in a ring topology with each other. Its input is a node function $i \rightarrow r \rightarrow (o,r)$ in which r serves as the intermediary output that gets send to the neighbour of each node. This data is sent over direct communication channels, the so called 'remote data'. We depict it in Appendix, Fig. B 10.

We can rewrite this functionality easily with the use of *loop* as the definition of the node function, arr(i,r)(o,r), after being transformed into an arrow, already fits quite neatly into the *loop*'s $arr(a,b)(c,b) \rightarrow arr\ a\ c$. In each iteration we start by rotating the intermediary input from the nodes $[fut\ r]$ with $second\ (rightRotate>>> lazy)$ (Fig. B 7). Similarly to the pipe from Section 7.1 (Fig. 21), we have to feed the intermediary input into our lazy (Fig. B 7) arrow here, or the evaluation would fail to terminate. The reasoning is explained by Loogen (2012) as a demand problem.

Next, we zip the resulting $([i],[fut\,r])$ to $[(i,fut\,r)]$ with $arr\ (uncurry\,zip)$ so we can feed that into a our input arrow $arr\ (i,r)\ (o,r)$, which we transform into $arr\ (i,fut\,r)\ (o,fut\,r)$ before lifting it to $arr\ [(i,fut\,r)]\ [(o,fut\,r)]$ to get a list $[(o,fut\,r)]$. Finally we unzip this list into $([o],[fut\,r])$. Plugging this arrow $arr\ ([i],[fut\,r])\ ([o],fut\,r)$ into the definition of loop from earlier gives us $arr\ [i]\ [o]$, our ring arrow (Fig. 25). This combinator can, for example, be used to calculate the shortest paths in a graph using Warshall's algorithm.

Note that the Par Monad version of the *ArrowParallel* version presented in this paper (Fig. 9) does not work with the looping behaviour in the *ring* skeletons. Whenever *runPar* is invoked, strictness is enforced, which means that the *lazy* operation in the definition of *ring* will not work.

7.3 Torus skeleton

If we take the concept of a *ring* from Section 7.2 one dimension further, we obtain a *torus* skeleton (Fig. 26, 27). Every node sends ands receives data from horizontal and vertical

⁸ Available on Hackage: https://hackage.haskell.org/package/edenskel-2.1.0.0/docs/Control-Parallel-Eden-Topology.html

20:58

```
ring :: (ArrowLoop\ arr, Future\ fut\ r, ArrowParallel\ arr\ (i, fut\ r)\ (o, fut\ r)\ conf) \Rightarrow
  conf \rightarrow arr(i,r)(o,r) \rightarrow arr[i][o]
ring conf f =
  loop (second (rightRotate >>> lazy) >>> arr (uncurry zip) >>>
  parMap\ conf\ (second\ get >>> f >>> second\ put) >>> arr\ unzip)
```

Figure 25: Final definition of the *ring* skeleton.

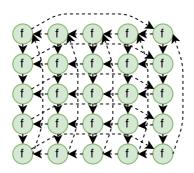

Figure 26: Schematic depiction of the torus skeleton.

neighbours in each communication round. With our Parallel Arrows we re-implement the torus combinator⁹ from Eden—yet again with the help of the ArrowLoop typeclass.

Similar to the ring, we once again start by rotating the input (Fig. B 7), but this time not only in one direction, but in two. This means that the intermediary input from the neighbour nodes has to be stored in a tuple ([[fut a]], [[fut b]]) in the second argument (loop only allows for two arguments) of our looped arrow arr([[c]],([[fut a]],[[fut b]]))([[d]],([[fut a]],[[fut b]]))and our rotation arrow becomes

```
second ((mapArr rightRotate >>> lazy) *** (arr rightRotate >>> lazy))
```

instead of the singular rotation in the ring as we rotate [[fut a]] horizontally and [[fut b]] vertically. Then, we once again zip the inputs for the input arrow with

```
arr (uncurry3 zipWith3 lazyzip3)
```

from ([[c]], ([[fut a]], [[fut b]])) to [[(c, fut a, fut b)]], which we then feed into our parallel execution.

This action is, however, more complicated than in the ring case as we have one more dimension of inputs to be transformed. We first have to shuffle all the inputs to then pass it into parMap conf (ptorus f) which yields $[(d, fut \ a, fut \ b)]$. We can then unpack this shuffled list back to its original ordering by feeding it into the specific unshuffle arrow we created one step earlier with arr length >>> arr unshuffle with the use of app:: arr (arr a b, a) c from the ArrowApply typeclass. Finally, we unpack this matrix $[[(d, fut \ a, fut \ b)]]$ with $arr (map \ unzip3) >>> arr \ unzip3 >>> threetotwo \ to \ get ([[d]], ([[fut \ a]], [[fut \ b]])).$

 $^{^9 \ \} Available \ \ on \ \ Hackage: \ \ https://hackage.haskell.org/package/edenskel-2.1.0.0/$ ${\tt docs/Control-Parallel-Eden-Topology.html}.$

```
torus:: (ArrowLoop arr, ArrowChoice arr, ArrowApply arr, Future fut a, Future fut b,
   ArrowParallel\ arr\ (c, fut\ a, fut\ b)\ (d, fut\ a, fut\ b)\ conf) \Rightarrow
   conf \rightarrow arr(c,a,b)(d,a,b) \rightarrow arr[[c]][[d]]
torus conf f =
   loop\ (second\ ((mapArr\ rightRotate>>> lazy)***(arr\ rightRotate>>> lazy))>>>
   arr (uncurry3 (zipWith3 lazyzip3)) >>>
   (arr length >>> arr unshuffle) &&& (shuffle >>> parMap conf (ptorus f)) >>> app >>>
   arr (map unzip3) >>> arr unzip3 >>> threetotwo)
ptorus :: (Arrow \ arr, Future \ fut \ a, Future \ fut \ b) \Rightarrow
   arr(c,a,b)(d,a,b) \rightarrow arr(c,fut\ a,fut\ b)(d,fut\ a,fut\ b)
ptorus f = arr (\lambda \sim (c, a, b) \rightarrow (c, get \ a, get \ b)) >>> f >>> arr (\lambda \sim (d, a, b) \rightarrow (d, put \ a, put \ b))
```

Figure 27: Definition of the torus skeleton. The definitions of lazyzip3, uncurry3 and threetotwo have been omitted and can be found in Fig. B 8

```
nodefunction :: Int \rightarrow ((Matrix, Matrix), [Matrix], [Matrix]) \rightarrow ([Matrix], [Matrix], [Matrix])
nodefunction\ n\ ((bA,bB),rows,cols) = ([bSum],bA:nextAs,bB:nextBs)
  where bSum = foldl' matAdd (matMult bA bB) (zipWith matMult nextAs nextBs)
     nextAs = take (n-1) rows
    nextBs = take (n-1) cols
```

Figure 28: Adapted *nodefunction* for matrix multiplication with the *torus* from Fig. 27.

As an example of using this skeleton (Loogen, 2012) showed the matrix multiplication using the Gentleman algorithm (1978). Their instantiation of the skeleton nodefunction can be adapted as shown in Fig. 28. If we compare the trace from a call using our arrow definition of the torus (Fig. 29) with the Eden version (Fig. 30) we can see that the behaviour of the arrow version and execution times are comparable. We discuss further examples on larger clusters and in a more detail in the next section.

Again, the implementation of the Par Monad version prevents this definition of the torus skeleton to work due to the reasons explained in the section about the ring skeleton in section 7.2.

8 Benchmarks

We will now discuss some benchmarks of our new PArrows DSL. We start by proving that we do not introduce any noteworthy

9 Conclusion

Arrows are a generic concept that allows for powerful composition combinators. To our knowledge we are the first ones to represent parallel computation with arrows. OL: that strange arrows-based robot interaction paper from 1993 or so! clearly discuss in related work done!

Arrows turn out to be a useful tool for composing in parallel programs. We do not have to introduce new monadic types that wrap the computation. Instead use arrows just

like regular sequential pure functions. This work features multiple parallel backends: the already available parallel Haskell flavours. Parallel Arrows feature an implementation of the *ArrowParallel* interface for Multicore Haskell, *Par* Monad, and Eden. With our approach parallel programs can be ported across these flavours with little to no effort. Performancewise, Parallel Arrows are on par with existing parallel Haskells, as they do not introduce any notable overhead.

The strictness problems of the *Par* Monad backend materializes with *ArrowLoop*. Additional work is required to ensure correct behaviour of the *Par* Monad in this context.

MB: mention ArrowLoop in Torus and Ring chapters OL: Parrows + accelerate = love? Metion port to Frege.

9.1 Future Work

Our PArrows DSL can be expanded to futher parallel Haskells. More specifically we target HdpH (Maier *et al.*, 2014), a modern distributed Haskell that would benefit from our Arrows notation. More Future-aware versions of Arrow combinators can be defined and existing can be further improved. We would look into more transparency of the DSL, it should basically infuse as little overhead as possible.

We are looking into more experiences with seamless porting of parallel PArrow-based programs across the backends. Of course, we are working on expanding both our skeleton library and the number of skeleton-based parallel programs that use our DSL to be portable across flavours of parallel Haskells. It would also be interesting to see a hybrid of PArrows and Accelerate. Ports of our approach to other languages like Frege or Java directly are in an early development stage.

A Utility Arrows

MB: Text außenrum bauen, siehe Omitted Function Definitions The second combinator:

```
second :: Arrow arr \Rightarrow arr ab \rightarrow arr (c,a) (c,b)
second f = arr swap >>> first f >>> arr swap
where swap (x,y) = (y,x)
```

is a mirrored version of first, used, e.g. in definition of ***.

20:58

Utility combinators for Parallel Arrows follow. We define map, foldl and zipWith on Arrows. The mapArr combinator (Fig. A 1) lifts any arrow $arr\ a\ b$ to an arrow $arr\ [a]\ [b]$ (Hughes, 2005b). Similarly, we can also define foldlArr (Fig. A 2) that lifts any arrow $arr\ (b,a)\ b$ with a neutral element b to $arr\ [a]\ b$.

```
mapArr::ArrowChoice\ arr \Rightarrow arr\ a\ b \rightarrow arr\ [a]\ [b]
mapArr\ f =
arr\ listcase>>>
arr\ (const\ [])\ |||\ (f***mapArr\ f>>>> arr\ (uncurry\ (:)))
listcase\ []=Left\ ()
listcase\ (x:xs)=Right\ (x,xs)
```

Figure A 1: The definition of map over Arrows and the listcase helper function.

Figure A 2: The definition of *foldl* over Arrows.

Finally, with the help of mapArr (Fig. A 1), we can define zipWithArr (Fig. A 3) that lifts any arrow arr(a,b)c to an arrow arr([a],[b])[c].

```
zipWithArr::ArrowChoice\ arr\Rightarrow arr\ (a,b)\ c \to arr\ ([a],[b])\ [c] zipWithArr\ f=(arr\ \lambda(as,bs)\to zipWith\ (,)\ as\ bs)>>> mapArr\ f
```

Figure A 3: *zipWith* over arrows.

These combinators make use of the ArrowChoice type class which provides the \parallel combinator. It takes two arrows $arr\ a\ c$ and $arr\ b\ c$ and combines them into a new arrow $arr\ (Either\ a\ b)\ c$ which pipes all $Left\ a$'s to the first arrow and all $Right\ b$'s to the second arrow:

```
(\parallel)::ArrowChoice arr a c \rightarrow arr b c \rightarrow arr (Either a b) c
```

With the zipWithArr combinator we can also write a combinator listApp, that lifts a list of arrows $[arr\ a\ b]$ to an arrow $arr\ [a]\ [b]$.

```
listApp :: (ArrowChoice\ arr, ArrowApply\ arr) \Rightarrow [arr\ a\ b] \rightarrow arr\ [a]\ [b]
listApp\ fs = (arr \$ \lambda as \rightarrow (fs, as)) >>> zipWithArr\ app
```

Note that this additionally makes use of the ArrowApply typeclass that allows us to evaluate arrows with $app :: arr(arr \ ab, a) \ c$.

B Omitted Function Definitions

We have omitted some function definitions in the main text for brevity, and redeem this here. We warp Eden's build-in Futures in PArrows as in Figure B 5, where *rd* is the accessor function for the *RD* wrapped inside *RemoteData*. Furthermore, in order for these *Future* types to fit with the *ArrowParallel* instances we gave earlier, we have to give the necessary *NFData* and *Trans* instances, the latter are only needed in Eden. The *Trans* instance does not have any functions declared as the default implementation suffices here. Furthermore, because *MVar* already ships with a *NFData* instance, we only have to supply a simple delegating *NFData* instance for our *RemoteData* type, where *rd* simply unwraps *RD*. The *Trans* instance does not have any functions declared as the default implementation suffices:

```
instance NFData (RemoteData a) where rnf = rnf \circ rd instance Trans (RemoteData a)
```

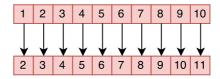

Figure B 1: Schematic depiction of parMap.

 $parMap :: (ArrowParallel \ arr \ a \ b \ conf) \Rightarrow conf \rightarrow (arr \ a \ b) \rightarrow (arr \ [a] \ [b])$ $parMap \ conf \ f = parEvalN \ conf \ (repeat \ f)$

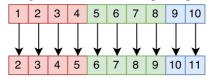

Figure B 3: Schematic depiction of parMapStream.

 $parMapStream :: (ArrowParallel \ arr \ a \ b \ conf, ArrowChoice \ arr, ArrowApply \ arr) \Rightarrow conf \rightarrow ChunkSize \rightarrow arr \ a \ b \rightarrow arr \ [a] \ [b] \\ parMapStream \ conf \ chunkSize \ f = parEvalNLazy \ conf \ chunkSize \ (repeat \ f)$

Figure B 4: Definition of parMapStream.

Figures B 1–B 4 show the definitions and a visualizations of two parallel *map* variants, defined using *parEvalN* and its lazy counterpart.

Arrow versions of Eden's *shuffle*, *unshuffle* and the definition of *takeEach* are in Figure B 6. Similarly, Figure B 7 contains the definition of arrow versions of Eden's *lazy* and *rightRotate* utility functions. Fig. B 8 contains Eden's definition of *lazyzip3* together with the utility functions *uncurry3* and *threetotwo*. The full definition of *farmChunk* is in Figure B 9. Eden definition of *ring* skeleton is in Figure B 10. It follows Loogen (2012).

```
data RemoteData a = RD \{ rd :: RD \ a \}

instance (Trans \ a) \Rightarrow Future \ RemoteData \ a \ where

put = arr \ (\lambda a \rightarrow RD \ \{ rd = release \ a \})

get = arr \ rd >>> arr \ fetch
```

Figure B 5: RD-based RemoteData version of Future for the Eden backend.

```
shuffle::(Arrow\ arr)\Rightarrow arr\ [[a]]\ [a] shuffle=arr\ (concat\circ transpose) unshuffle::(Arrow\ arr)\Rightarrow Int\rightarrow arr\ [a]\ [[a]] unshuffle\ n=arr\ (\lambda xs\rightarrow [takeEach\ n\ (drop\ i\ xs)\ |\ i\leftarrow [0\mathinner{.\,.} n-1]]) takeEach::Int\rightarrow [a]\rightarrow [a] takeEach\ n\ ([]=[] takeEach\ n\ (x:xs)=x:takeEach\ n\ (drop\ (n-1)\ xs)
```

Figure B 6: Definitions of *shuffle*, *unshuffle*, *takeEach*.

The parEval2 skeleton is defined in Figure B 11. We start by transforming the (a,c) input into a two-element list $[Either\ a\ c]$ by first tagging the two inputs with Left and Right and wrapping the right element in a singleton list with return so that we can combine them with $arr\ (uncurry\ (:))$. Next, we feed this list into a parallel arrow running on two instances of f+++g as described above. After the calculation is finished, we convert the resulting $[Either\ b\ d]$ into ([b],[d]) with $arr\ partitionEithers$. The two lists in this tuple contain only one element each by construction, so we can finally just convert the tuple to (b,d) in the last step.

C Syntactic Sugar

For basic arrows, we have the *** combinator (Fig. 6) which allows us to combine two arrows $arr\ a\ b$ and $arr\ c\ d$ into an arrow $arr\ (a,c)\ (b,d)$ which does both computations at once. This can easily be translated into a parallel version *** with the use of parEval2, but for this we require a backend which has an implementation that does not require any configuration (hence the () as the conf parameter):

```
(|***|):: (ArrowChoice\ arr, ArrowParallel\ arr\ (Either\ a\ c)\ (Either\ b\ d)\ ())) \Rightarrow arr\ a\ b \to arr\ c\ d \to arr\ (a,c)\ (b,d) (|***|) = parEval2\ ()
```

We define the parallel &&& in a similar manner to its sequential pendant &&& (Fig. 6):

```
(|\&\&\&|) :: (ArrowChoice\ arr, ArrowParallel\ arr\ (Either\ a\ a)\ (Either\ b\ c)\ ()) \Rightarrow arr\ a\ b \to arr\ a\ c \to arr\ a\ (b,c) \\ (|\&\&\&|)f\ g = (arr\,\$\,\lambda a \to (a,a)) >>> f\ |***|g
```

Arrows for Parallel Computations

```
lazy :: (Arrow \ arr) \Rightarrow arr \ [a] \ [a]
lazy = arr \ (\lambda \sim (x:xs) \rightarrow x: lazy \ xs)
rightRotate :: (Arrow \ arr) \Rightarrow arr \ [a] \ [a]
rightRotate = arr \$ \lambda list \rightarrow \mathbf{case} \ list \ \mathbf{of}
[] \rightarrow []
xs \rightarrow last \ xs: init \ xs
```

Figure B 7: Definitions of *lazy* and *rightRotate*.

```
\begin{split} &lazyzip3::[a] \rightarrow [b] \rightarrow [c] \rightarrow [(a,b,c)] \\ &lazyzip3 \ as \ bs \ cs = zip3 \ as \ (lazy \ bs) \ (lazy \ cs) \\ &uncurry3::(a \rightarrow b \rightarrow c \rightarrow d) \rightarrow (a,(b,c)) \rightarrow d \\ &uncurry3f \ (a,(b,c)) = f \ a \ b \ c \\ &threetotwo::(Arrow \ arr) \Rightarrow arr \ (a,b,c) \ (a,(b,c)) \\ &threetotwo = arr \$ \lambda \sim (a,b,c) \rightarrow (a,(b,c)) \end{split}
```

Figure B 8: Definitions of *lazyzip3*, *uncurry3* and *threetotwo*.

```
farmChunk :: (ArrowParallel \ arr \ a \ b \ conf, ArrowParallel \ arr \ [a] \ [b] \ conf, \\ ArrowChoice \ arr, ArrowApply \ arr) \Rightarrow \\ conf \rightarrow ChunkSize \rightarrow NumCores \rightarrow arr \ a \ b \rightarrow arr \ [a] \ [b] \\ farmChunk \ conf \ chunkSize \ numCores \ f = \\ unshuffle \ numCores \ >>> \\ parEvalNLazy \ conf \ chunkSize \ (repeat \ (mapArr \ f)) >>> \\ shuffle \end{aligned}
```

Figure B 9: Definition of farmChunk.

```
\begin{array}{l} \mathit{ringSimple} :: (\mathit{Trans}\ i, \mathit{Trans}\ o, \mathit{Trans}\ r) \Rightarrow (i \rightarrow r \rightarrow (o,r)) \rightarrow [i] \rightarrow [o] \\ \mathit{ringSimple}\ f\ is = os \\ \mathbf{where}\ (os, \mathit{ringOuts}) = \mathit{unzip}\ (\mathit{parMap}\ (\mathit{toRD}\ \$\,\mathit{uncurry}\ f)\ (\mathit{zip}\ is\ \$\,\mathit{lazy}\ \mathit{ringIns})) \\ \mathit{ringIns} = \mathit{rightRotate}\ \mathit{ringOuts} \\ \mathit{toRD} :: (\mathit{Trans}\ i, \mathit{Trans}\ o, \mathit{Trans}\ r) \Rightarrow ((i,r) \rightarrow (o,r)) \rightarrow ((i,\mathit{RD}\ r) \rightarrow (o,\mathit{RD}\ r)) \\ \mathit{toRD}\ f\ (i,\mathit{ringIn}) = (o,\mathit{release}\ \mathit{ringOut}) \\ \mathbf{where}\ (o,\mathit{ringOut}) = f\ (i,\mathit{fetch}\ \mathit{ringIn}) \\ \mathit{rightRotate} :: [a] \rightarrow [a] \\ \mathit{rightRotate}\ xs = \mathit{last}\ xs : \mathit{init}\ xs \\ \mathit{lazy} :: [a] \rightarrow [a] \\ \mathit{lazy} \sim (x : xs) = x : \mathit{lazy}\ xs \\ \end{array}
```

Figure B 10: Eden's definition of the *ring* skeleton.
